

PAD WEAR COMPENSATOR FOR A DISC BRAKE CALIPER

RELATED APPLICATIONS

5 This application claims priority from United States Provisional Patent Application
Serial No.60/195,560, filed April 6, 2000, entitled "Mechanical Disc Brake Caliper."

TECHNICAL FIELD

10 The present invention is directed toward disc brakes, and more particularly toward a
pad wear compensator for a disc brake caliper.

BACKGROUND ART

15 Disc brakes are being included on more and more bicycles as consumers are ever
increasingly demonstrating a preference for disc brakes over conventional rim brakes such as
caliper brakes, cantilever brakes and side pull cantilever brakes. While both mechanical and
hydraulic disc brakes have been available for bicycles for many years, only recently have there
been advances in disc brake caliper design that have made disc brakes sufficiently lightweight,
reliable and inexpensive to satisfy consumer preferences. While more efficient and powerful
caliper drive mechanisms are evolving, to date manufacturers of disc brakes have not
20 adequately addressed consumer need for ease of adjustment and maintenance of these caliper
brakes. One area of particular concern is structures for compensating for pad wear.

25 One known pad wear compensator provides a set screw that can be advanced within
a caliper housing to advance an operatively associated brake pad as the pad wears. The set
screw resides within a threaded bore in the housing and requires a turning tool such as a hex
wrench to advance the pad. In addition, to lock the pad in a select position, a second locking
screw is threadably engaged in the bore to lock the adjustment screw in place. This structure,
while allowing for advancement of the pad to compensate for pad wear, is extremely
cumbersome to use, requiring the removal of one screw and the turning of two screws as well
as the use of a separate tool to make an adjustment. In addition, because the adjustment screw
30 resides within the threaded bore, there is no reliable way to gauge how far the pad has been

extended so as to assess remaining pad life. Furthermore, the structure fails to provide any indexing to insure select axial advancement of the brake pad as the adjustment screw is rotated.

Another known pad wear compensator provides a knob which can be rotated to advance the caliper housing relative to a disc operatively associated with the housing so as to compensate for brake pad wear. While this structure overcomes some of the complexity and tool requirements of the structure discussed in the preceding paragraph, it still has numerous deficiencies. Most notably, by providing for advancement of the entire housing relative to the disc as opposed to simply advancement of the pad itself relative to the housing and the disc as it wears, the advancement structure must reside outside of the housing and is thus subject to damage and abuse in use. In addition, while this structure does allow for observation of how far the housing has been advanced relative to the disc, it does not provide a reliable indication of pad wear, as adjustment of the housing may be dictated by other factors such as disc alignment.

Yet another known pad wear compensator provides a knob which threadably engages a caliper housing. The knob can be rotated relative to the caliper housing and thus advanced and retracted axially of the housing. As the knob is rotated to advance it relative to the housing it also advances a pad actuation mechanism along with a pad assembly associated therewith to advance the pad assembly. The opposing pad is fixed against movement relative to the housing. However, the housing itself is moveable relative to a disc so that by movement of the caliper housing and movement of the pad wear compensation knob, pad wear on each of the pads can be compensated for. This structure is still very cumbersome in that only one pad can be advanced relative to the housing. In addition, the knob both rotates and is advanced relative to the housing, providing a potential avenue for grit and other contaminants to effect smooth operation of the caliper actuation mechanism. Finally, because the housing itself is moveable relative to the disc to enable compensation of the fixed pad, there is no reliable indication of how much wear the respective pads have experienced.

The present invention is intended to overcome one or more of the problems discussed above.

SUMMARY OF THE INVENTION

A disc brake caliper includes a housing containing a pair of opposing brake pad assemblies configured to reside on opposite sides of a disc operatively associated therewith. At least one of the brake pad assemblies is advanced and retracted relative to the disc by a drive mechanism along an advancement axis to effect braking. A pad wear compensation apparatus is operatively associated with at least one of the brake pad assemblies to advance the brake pad assembly along the advancement axis as it wears. The pad wear compensation apparatus includes an adjustment knob attached to the housing for rotation about a rotation axis and fixed against axial movement. A rotary to linear linkage between the at least one brake pad assembly and the knob provides axial advancement of the brake pad assembly relative to the housing upon axial rotation of the knob in a select direction. The pad wear compensation apparatus preferably further includes an indicator visually observable outside the housing. The indicator is operatively associated with the rotary to linear linkage to advance with the brake pad assembly as the adjustment knob is rotated in a select direction. The rotary to linear linkage preferably includes the indicator. The indicator has a leading portion and a trailing portion extending into an orifice on the knob along the rotation axis. The trailing portion of the indicator and the orifice are configured to permit axial movement of the indicator relative to the knob but to prevent radial movement of the indicator relative to the knob so that as the knob is rotated about the rotation axis the indicator is rotated about the rotation axis. The leading portion of the indicator preferably has threads which engage complimentary threads within the housing that are fixed against radial movement relative to the indicator and fixed against movement along the advancement axis relative to the brake pad assembly. Thus, as the knob is rotated in the select direction, the indicator is advanced along the advancement axis relative to the housing. A link is provided between the indicator and the brake pad so that as the indicator is advanced along the advancement axis the brake pad assembly is advanced. A tactile indicator may be associated with the knob for providing a tactile indication of advancement of the brake pad assembly along the advancement axis a

select amount as the knob is rotated in the select direction. The tactile indicator preferably includes index knurls within the housing that are fixed against rotation relative to the knob and complimentary detents operatively associated with the knob engaging the knurls as the knob is rotated relative to the detents.

5 A second aspect of the invention is a mechanical disc brake caliper including a caliper housing. First and second brake pad assemblies each having a leading brake pad reside within the housing on opposite sides of a disc operatively associated with the caliper. A drive within the housing is operatively associated with the first brake pad assembly for advancing and retracting the first brake pad assembly relative to the disc along an advancement axis to effect
10 braking by advancing the leading brake pad into contact with the disc. A pad wear compensation apparatus is operatively associated with the first brake pad assembly to advance the brake pad assembly along the advancement axis as the brake pad wears. The pad wear compensation apparatus includes an adjustment knob attached to the housing for rotation about a rotation axis. An indicator has a leading portion within the housing and a trailing
15 portion engaging the knob along the rotation axis. The trailing portion and the knob are configured to permit axial movement of the indicator relative to the knob but to prevent rotational movement of the indicator relative to the knob so that as the knob is rotated about the rotation axis the indicator is rotated about the rotation axis. Threads on the leading portion of the indicator engage complimentary threads attached to the drive that are fixed
20 against radial movement relative to the indicator and fixed against movement along the advancement axis relative to the drive. Thus, as the knob is rotated in a select direction, the indicator is advanced along the advancement axis relative to the drive. A link between the indicator and the first brake pad assembly advances the first brake pad assembly along the advancement axis as the indicator is advanced. The knob preferably has an orifice that
25 extends through the knob along the rotation axis and the distal end of the indicator is axially received therein. The orifice and the distal end of the indicator are configured to allow axial movement of the distal end within the orifice but to prevent rotational movement of the distal end relative to the knob. The distal end of the indicator is visibly observable through the orifice to provide a visual indication of how far the pad assembly is advanced. Preferably a

tactile indicator is operatively associated with the knob for providing a tactile indication of advancement of the brake pad assembly along the advancement axis a select amount as the knob is rotated in the select direction.

Yet another aspect of the present invention is a pad wear compensation apparatus for a disc brake caliper. The disc brake caliper has a housing containing a pair of opposing brake pad assemblies configured to reside on opposite sides of a disc operatively associated with the caliper housing. At least one brake pad assembly is advanced and retracted relative to the disc along an advancement axis by a drive to effect braking. The pad wear compensation apparatus is operatively associated with at least one brake pad assembly to advance the brake pad along the advancement axis as it wears. The pad wear compensation apparatus includes an adjustment member attached to the housing for rotation about a rotation axis. A rotary to linear linkage between the at least one brake pad assembly and the adjustment member provides for axial advancement of the brake pad assembly relative to the housing upon axial rotation of the knob in a select direction. An indicator is associated with the knob for providing a tactile indication of advancement of the pad assembly along the advancement axis a select amount as the knob is rotated in the select direction. The tactile indicator preferably includes indexing knurls within the housing that are fixed against rotation relative to the adjustment member and complimentary detents operatively associated with the adjustment member which engage the knurls as the knob is rotated relative to the detents. The adjustment member may be fixed against axial movement relative to the housing.

Another aspect of the present invention is a method for attaching a disc brake caliper of a bicycle disc brake to a bicycle frame. The caliper has a caliper housing and a pair of brake pads within the housing positioned to receive a planer disc brake operatively associated with the caliper between the pair of brake pads. A drive advances at least one of the brake pads into contact with the disc along an advancement axis. The method includes providing a pad wear compensator within the housing for advancing and retracting the pads along the advancement axis relative to the housing. An attachment structure is also provided between the caliper housing and the bicycle frame allowing for infinite variation in the angle of incidence between the advancement axis and the plane of the disc. The pads are advanced

relative to the housing into flush contact with the disc by using the pad wear compensation apparatus. With the pads advanced into flush contact with the disc, the housing is secured to the frame to prevent movement of the caliper housing relative to the frame. Thereafter, the pads are retracted using the pad wear compensation apparatus a select distance from the disc to allow for free rotation of the disc between the pads.

The pad wear compensation apparatus of the present invention allows for quick and easy advancement of the brake pads relative to the housing to compensate for brake pad wear. The knobs allow for this adjustment to be made without tools, allowing the adjustment to be made anywhere and at any time with minimal effort by the user. Because the knobs rotate but do not advance axially with the remainder of the pad wear compensation apparatus, the opportunity for grit or the like contaminating the apparatus is minimized. The tactile indicator of the pad wear compensation apparatus gives immediate tactile feedback to a user to indicate a select distance of pad advancement for a select increment of rotation of the knob. The pad wear compensation apparatus also includes a visual indicator giving an immediate visual indication to the user of how far the brake pad has been advanced relative to the housing. In this manner a user can continuously monitor the amount of pad wear left so as to minimize the possibility of excessive pad wear during an extended ride which could cause scoring and ultimately the ruining of an associated disc. Finally, the pad wear compensation apparatus enables a fast and reliable method for attaching a caliper housing to a bicycle frame in proper alignment with a disc. All these many advantages are provided by the pad wear compensation apparatus that consists of simple mechanical elements that can be produced and assembled inexpensively and which provide highly reliable and convenient adjustment.

BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 1 is a perspective view showing the mechanical disc brake caliper of the present invention mounted to a fork of a bicycle in operative engagement with a brake disc;

Fig. 2 is the mechanical disc brake caliper of Fig. 1 including an adaptor for mounting to a frame with different mounts;

Fig. 3A is a front elevation view of the mechanical disc brake caliper of Fig. 1 including a floating cable stop;

Fig. 3B is identical to Fig. 3A except it further includes an alternate embodiment of the floating cable stop;

5 Fig. 3C is a cross-section of the floating cable stop taken along line 3C-3C of Fig. 3A;

Fig. 4A is an exploded perspective view of the mechanical disc brake caliper of Fig. 1;

Fig. 4B is an exploded perspective view from a perspective rotated 180° from that of Fig. 4A;

10 Fig. 4C is a bottom perspective view of a clamp plate in accordance with the present invention;

Fig. 5 is a cross-section of the mechanical disc brake caliper taken along line 5-5 of Fig. 3A with the brake pads retracted;

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

A mechanical disc brake caliper 10 in accordance with the present invention is shown in Fig. 1 mounted to a frame or, more particularly, a front fork 12 of a bicycle in operative

engagement with a disc 14. As shown in Figs. 1-3, the caliper 10 is mounted to a front fork 12 for use with a front wheel. For use with the rear wheel, the caliper is typically mounted to the seat stay, chain stay, drop out plate, after market adapter or the like. The disc 14 in turn is rigidly mounted to the hub of a wheel assembly by the bolts 16. For the sake of clarity, the bicycle wheel and hub are not shown.

The mechanical disc brake caliper consists of a caliper housing 18 having a pair of mounting feet 20, 22 extending therefrom for attachment to a corresponding pair of internally threaded attachment bosses 24, 26 which extend from the front fork 12. A pair of mounting bolts 28 secure the mounting feet 20, 22 to the attachment bosses 24, 26. The mounting feet preferably include elongate slots 27 (see Fig. 5) receiving the mounting bolts 28 and complimentary pairs of concave/convex washers 30 to provide for adjustable attachment of the mechanical disc brake caliper to a bicycle frame. Such an attachment structure is described in detail in applicant Wayne Lumpkin's, co-pending Patent Application Serial No. 09/383,121, the disclosure of which is hereby incorporated in its entirety herein.

As seen in Fig. 1, a lever arm 32 is pivotally attached at a first end 34 to the caliper housing 18. A second end of the lever arm 36 has a cable clamp 38 which secures an end of the cable 40. The cable 40 is directed through a cable feed 42 attached to the caliper housing 18 with a cable housing 44 abutting the cable feed 42. While the operation of the mechanical disc brake will be described in considerably greater detail below, it is useful at the outset to understand that the mechanical disc brake caliper is actuated by tension being applied to an opposite end of the cable 40 by a cable actuator such as a conventional cable brake lever (not shown) and this tension causes the lever arm 32 to pivot about pivot axis 46 in the direction of arrow 48 so that the second end of the lever arm 36 is drawn toward the cable guide 42 to advance a brake pad into contact with the disc 14 by a rotary to linear linkage between the first end 34 of the lever arm 32 and the brake pad.

Fig. 2 shows the mechanical disc brake caliper 10 mounted to a front fork 12' having internally threaded attachment bosses 24' and 26' with an axis parallel to the axis of rotation of the disc 14. The mechanical disc brake caliper 10' is in all manner identical to the mechanical disc brake 10 described above with regard to Fig. 1. For simplicity, all

unnecessary corresponding reference numbers have been omitted. An adapter bracket 60 is fastened by a pair of bolts 62 to the attachment bosses 24', 26' and includes a pair of internally threaded receptor bores 64 that enable the caliper housing 18 to be attached to the front fork 12' in an identical position relative to the disc 14 described above with respect to Fig. 1. Thus, the adapter bracket provides an equivalent mounting surface to that provided by the attachment bases 24, 26, as shown in Fig. 1.

Fig. 3A is a front elevation view of the mechanical disc brake caliper 10 mounted to a bicycle frame 12 as illustrated in Fig. 1. Fig. 3 differs from Fig. 1 by the inclusion of the floating cable stop 70, which will be described in greater detail below.

The mechanical disc brake caliper 10 is shown in an exploded perspective view in Fig. 4A. Fig 4B is identical to Fig. 4A, only the perspective is rotated 180°. First and second brake pad assemblies 72, 74 consist of mirror image backing plates 76, 78 each having a trailing surface 80 including a post receiving receptacle 81 and a leading surface 82 to which a brake pad 84 is permanently adhered. When the mechanical disc brake caliper is operatively associated with a disc 14, the disc 14 resides between the pads 84 of the first and second brake pad assembly 72, 74 which are held in place in part by a pad retention clip 85 in a manner which will be described in greater detail below.

As oriented in Fig. 4A, the second brake pad assembly 74 is also known as the back or inboard brake pad assembly. A pad wear compensator 73 for the inboard pad assembly includes inboard pressure foot 86, which as discussed below, functions as an indicator. The inboard brake pad assembly 74 is attached to the inboard pressure foot 86 by means of a washer-shaped magnet 88 which is adhered to a cooperatively shaped receptacle 90 in the leading surface 92 of the inboard pressure foot 86. An axial post 94 extends through the hole in the washer-shaped magnet 88 and protrudes beyond the leading surface 92 to engage the post receiving receptacle 81 in the trailing surface of the backing plate. A trailing portion or indicator dog 96 having a rectangular cross-section extends from a trailing surface of the inboard pressure foot 86 along the same axis of the axial post 94. The edge of the inboard pressure foot 86 is threaded as indicated at 100 between the leading surface 92 and the trailing surface 98. The threads 100 are sized to threadably engage complimentary threads 102 in the

Split ring 144 is sized to be received in the annular groove 140. Ball bearing 146 is sized to be received in and to extend axially from the axial cup 142.

5 An indicator foot screw 148 has a head 149 with a leading surface 150 which abuts the ball bearing 146. Behind the head 149 is a shaft 152 which is threaded adjacent to the head 149 as indicated at 154. The trailing end of the shaft 152 has a pair of flats 156 (one shown in Fig. 4A) on opposite sides. The indicator foot screw 148 is an integral part of a pad wear compensator 153 for the outboard brake pad assembly.

10 Drive cam 158 has an enlarged diameter base 160 having a plurality of equally spaced curved, ramped grooves 162 in its trailing surface. The preferred embodiment has three ramped grooves 162 spaced at 120°. A cylindrical shaft 164 extends rearward of the enlarged diameter base 160 and has an axial bore 166 which extends axially through the drive cam 158. As best viewed in Fig. 5, the axial bore includes a threaded inner diameter portion 168 which threadably engages the threaded portion 154 of the foot screw 148 with the shaft 152 extending rearwardly from the axial bore 166. Further referring to Fig. 5, an inwardly
15 extending flange 170 acts as a stop against a rearward portion of the head 149. The distal end of the outside cylindrical shaft 164 is threaded at 172 and adjacent the treaded portion 172 is a hex portion 174. One of three ball bearings 176 resides in each ramped groove 162. The outer diameter of the enlarged diameter base 160 is sized to fit snugly within the inner diameter of the outside cylinder 128 and have a sealing relationship with the dust seal 132 as
20 best seen in Figs. 5 and 7.

Fixed cam 178 has a generally cylindrical body 180 with a constant inner diameter orifice 182. An intermediate step 184 has a spring tension limiting boss 186 which extends axially onto the cylindrical body 180. A leading step 188 has an outer diameter greater than that of the intermediate step 184 and an enlarged outside diameter annular flange 190 rises
25 from the leading step 188 adjacent the intermediate step 184. A locking boss 192 extends toward the leading surface 193 collinearly with the spring tension limiting boss 186 at a height matching that of the enlarged outer diameter annular flange 190. The locking boss 192 is sized to key into a receiving slot 194 in the inner diameter of the outside cylinder 128 to lock the fixed cam 178 against axial rotation (see Fig. 4A). In addition, the leading surface of the

enlarged outer diameter annular flange 190 abuts a step 196 in the inner diameter of the outside cylinder 128 to halt axial insertion of the fixed cam 178 into the outside cylinder 128 from the opened end as viewed in Fig. 4A. The engaged relationship can best be seen in Fig. 5. The leading surface 193 of the fixed cam 178 is best viewed in Fig. 4B. The leading surface has a plurality of equally radially spaced ramped grooves corresponding to the ramped grooves of the drive cam 158. Fig. 4B shows three ramped grooves 200 spaced at 120° which correspond to the ramped grooves 162 of the drive cam 158, only with the ramps extending radially in opposite directions when aligned as shown in Figs. 4A, 4B and 5-7. A ball bearing 176 resides between each ramped groove pair 162, 200 as best viewed in Figs. 5-7. Referring to Fig. 5, with balls residing in the grooves 162, 200, the grooves and ball bearings act as an angular contact bearing which is able to accommodate axial loads on the drive cam exerted by the lever arm 32. In addition, the ramped grooves self-center the drive cam shaft 164 within the inner diameter 182 of the fixed cam 178 with the drive cam under an axial load. This feature eliminates the need for an optional split bushing (not shown) being press fit in the inner diameter 182 of the fixed cam 178. It further eliminates friction between the drive cam shaft 164 and fixed cam 178. It further reduces needs for tight tolerances between the drive cam shaft 164 and fixed cam 178, thus eliminating the need for costly centerless grinding of the drive cam shaft and reaming of the fixed cam bore 182. These combined advantages significantly improve performance and minimize parts cost and assembly complexity and attendant cost.

When the fixed cam is seated within the outside cylinder 128 as described above and as viewed in Fig. 5, it is locked against axial movement by locking ring 204 which has a threaded outer diameter 206 and evenly spaced engagement slots 208 in the inner diameter 210. The inner diameter is sized to snugly receive the intermediate step 184 of the fixed cam 178 and the engagement slots 208 allow for engagement by a special turning tool (not shown) so that the threaded outer diameter 206 can be brought into threaded engagement with corresponding threads 212 in the inner diameter of the outside cylinder 128.

A generally washer-shaped spring tension biasing plate 220 has an inner diameter which snugly axially receives the intermediate step 184 of the fixed cam 178 and includes a

spring tension limiting slot 222 which receives the spring tension limiting boss 186. A cut in the outer diameter of the spring tension biasing plate forms a stop surface 224. Near the stop surface 224 is a hole 226. Return spring 228 has a pair of axially extending ends 230, 232. The inner diameter of the return spring 228 is large enough to axially receive the fixed cam 178 and the shaft 164 of the drive cam 158 as best viewed in Fig. 5. The axially extending end 230 is received in the hole 226 of the spring tension biasing plate 220 (see Fig. 5). A dust seal 234 defines an annular cover 236 for the return spring 228 as seen in Figs. 4B and Figs. 5-7. The inner diameter of the trailing orifice 238 is sized to receive and have a sealing relationship with the outer diameter of a leading flange 240 of the lever arm 32. A hole 242 in the trailing surface of the cover 236 receives the axially extending rod 232. The axially extending rod 232 in turn is received in the hole 244 near the first end 34 of the lever arm 32.

A hex orifice 246 near the first end 34 of the lever 32 axially receives the hex portion 174 of the cylindrical shaft 164 of the drive cam 158 with a hex inner diameter washer 248 therebetween to radially fix the lever arm 32 to the drive cam 158. Washer 252 abuts the trailing surface 254 and is sandwiched by a larger outer diameter washer 256. The larger outer diameter washer 256 has a number of equally radially spaced indexing knurls 258 in its outer diameter. The washers 252, 256 and the lever arm 32 are axially secured to the cylindrical shaft 164 of the drive cam 158 by nut 260 which threadably engages the threaded portion 172 of the cylindrical shaft 164.

An outboard knob 264 has a knurled edge 266 and an orifice or axial hole 268 sized and dimensioned to snugly receive the flats 156 of the trailing end of the foot screw 148 therein, as illustrated in Fig. 5. Referring to Fig. 4B, a plurality of axially inwardly extending legs 270 are equally radially spaced in an inside surface of the outer knob 264. At the distal end of each axially inwardly extending leg 270 is an inwardly protruding barb 272. An outside indexing spring clip 274 has a plurality of axially extending bars 276 each having an inwardly extending detent 278 near its distal end. The axially extending bars 276 are sized to snugly fit between the axially inwardly extending legs 270 of the outboard knob (see Fig. 4A). With the outside indexing spring clip axially engaged with the outer knob 264 in the

orientation illustrated in Fig. 4A, the outer knob 264 is axially advanced over the nut 260 and the inwardly protruding barbs 272 lockingly engage the outer diameter edge of the large outer diameter washer 256 to lock the outer knob 264 against axial movement. When attached in the this manner, the inwardly extending detents 278 of the outside indexing spring clip engage the indexing knurls 258 of the larger outer diameter washer 256. This can be best seen in detail with reference to Figs. 14 and 5. As will be described further below, the complimentary detents and indexing knurls provide a tactile indication of pad advancement as the outboard knob 264 is rotated.

With reference to Figs. 4A, 12 and 13, the cable feed 42 consists of a mount 284 which is preferably integrally cast with the housing 18. The mount 284 includes an orifice 286 centered along a guide axis 288. A cylindrical housing stop feral 290 has a cylindrical main body 292 having an outer diameter dimensioned to fit freely yet snugly within the orifice 286. A minor boot retention barb 294 extends axially from a leading end of the housing stop feral. A major boot retention barb 296 extends axially from a trailing end of the housing stop feral. An annular retention flange 298 extends radially from the main body 292 adjacent to the major boot retention barb 296 and forms a stop which halts axial insertion of the housing stop feral 290 into the orifice 286, as best seen in Fig. 12. Further referring to Fig. 12, the inside of the housing stop feral 290 has a trailing portion having an inner diameter slightly larger than that of a standard cable housing to axially receive the cable housing 44 therein. An annular flange 302 extends inwardly to define a cable guide orifice 304. The inner diameter of the minor boot retention barb 306 is of a size between that of the trailing inner diameter 300 and the cable guide orifice 304.

A hollow minor retention boot 310 is molded of an elastimeric material and at its trailing edge has an inwardly extending annular flange 312 configured to lockingly engage with the minor boot retention barb 294 of the housing stop feral 290. With the housing stop feral 290 inserted in the orifice 286 as illustrated in Fig. 12 and the minor retention boot mounted with the inwardly extending annular flange 312 engaging the minor boot retention barb 294, the housing stop feral is secured against removal from the orifice 286. The minor retention boot has a leading nipple 314 having a leading hole 316 with an inner diameter

a ~ cont. slightly less than the outer diameter of the standard bicycle brake cable 40. In this manner, the leading nipple forms a wipe seal with the brake cable 40 as seen in Fig. 12.

5 A hollow major retention boot 320 molded of an elastomeric material has an inwardly extending annular flange 322 sized to lockingly engage with the major boot retention barb 296 on the trailing end of the housing stop feral 290 as best viewed Fig. 12. The trailing end 324 has a tapered inner diameter, which at the extreme trailing end is slightly smaller than the outer diameter of the standard cable housing to form a sealing relationship therewith.

10 With the lever arm 32 pivotally attached to the housing as illustrated in Figs. 1-3B, 10 and 11, a curved horn 330 defining an axially flat, radially curved cable guide surface 332 extends from a trailing end of the second end 36 of the lever 32. The curved horn 330 curves about the axis of rotation 46 of the lever arm 32. In the preferred embodiment, the curved horn is eccentric about the axis as illustrated schematically in Fig. 23 to provide for progressive increase in power as the lever is actuated by a cable 40. Alternatively, the curved horn can be concentric as shown in Fig. 24 or eccentric and regressive, which though not
15 illustrated, would require the curved horn to have an increasing radius as it extends toward its free end, essentially the opposite of the progressive horn illustrated in Fig. 23.

20 The cable clamp 38 consists of a screw 334 having a threaded shaft 336 sized to threadably engage an internally threaded bore in the lever arm 32 having an axis normal to the axis of rotation 46. In the preferred embodiment, a clamp plate 338 is secured between the head of the screw 334 and the second end 36 of the lever arm 32. The clamp plate has a tab 340 which is received in a notch 342 defined in the distal end of the lever arm 32 to fix the clamp plate against rotation. A groove 344 is formed in the underside of the clamp plate adjacent to the notch 342 to receive the cable 40 and has a number of protrusions 345 extending therein to improve the grip of the cable, as illustrated in Fig. 4B.

25 The curved horn 330 is configured so that with the mechanical disc brake caliper installed on a bike frame as illustrated in Figs. 1-3B, the guide axis 288 is essentially tangent to the free end of the curved horn 330. Essentially tangent means a cable 40 does not have a significant bend when it contacts the cable guide surface 332, but instead has a very gradual transition to the cable guide surface 332 as viewed in Fig. 3. When tension is applied to the

cable 40 by a tension actuator such as a conventional bicycle brake lever, the lever arm 32 is drawn toward the cable feed 42. Because of the radially curved cable guide surface 332, the fixed cable clamp and the fixed cable feed 42, no sharp bends are introduced to the cable 40 which might fatigue the cable and lead to premature failure of the cable, which could have disastrous results for a user.

In the embodiment illustrated in Fig. 1, the conventional cable housing extends from the trailing end of the major retention boot 320. An improvement to this conventional brake setup is to provide a floating cable stop 70 mating with the trailing inner diameter 300 of the housing stop ferrule 290 as illustrated in Fig. 3A. The floating cable stop 70 consists of a axially and radially rigid tube 348 made of a suitable material such as a metal like aluminum or stainless steel or an exceptionally rigid thermoplastic. As used herein, axially and radially rigid means the tube 348 has sufficient rigidity that it will not buckle about its lengthwise axis upon application of tension within the normal range of operating tensions applied to the cable 40 which runs within the tube 348. In the preferred embodiment, the tube 348 has a standard cylindrical cross-section (see Fig. 3C), although other cross-sections may be useful or desired. The outer diameter is preferably essentially the same to that of a standard cable housing 44 so that it can fit into a trailing end of the housing stop ferrule 290 in the same manner as the housing 44 as illustrated in Fig. 12. A connector feral 350 connects the tube 348 to a conventional cable housing 44. The conventional cable housing allows the cable to be axially deflected as may be required to attach the cable to a brake lever. A significant advantage of the floating cable stop 70 is that when it replaces conventional cable housings, it provides a straight path for the cable inside with minimal or no contact with the inner diameter of the tube. Over all but the shortest of lengths, the axially flexible cable housing will buckle about the lengthwise axis under application of even minor tension to the cable within and the resultant compression to the cable housing. Elimination of this buckling further reduces contact of the cable with the inner diameter of the tube and serves to further minimize friction on the cable. The floating cable stop can be deployed wherever there is a straight length of cable, independent of fixed housing stops on the bicycle frame. It also provides a protective barrier for the cable, much like conventional cable housing, but at a lesser weight.

the retention clip cavity. Pad retention clip 85 is shown in Fig. 16A installed within the retention clip cavity 378. The pad retention clip 85 has a base 382 with a pair of extending sidewalls or legs 384, 386 with a retention detent 388 near the far end of each leg protruding inwardly. Near the base 282 a plurality of retention barbs 390 extend laterally from the sidewalls or legs 384, 386. As illustrated in Fig. 16B, these retention barbs 390 are configured to snap fit with the engagement flanges 380 to lock the pad retention clip 85 within the retention clip cavity 378.

Referring back to Fig. 16A, the pad assembly 72 is installed by grasping the handle 392 and advancing the leading edge 368 into the mouth 362 along the engagement axis 394 and aligning the retention tab 370 with the pad retention clip 85 and further advancing the pad assembly so that the protrusions 370 mate within the retention detents 388. The pad can then be slid into the recess 364 along the advancement axis 366 to seat the pad assembly within the recess 364, as viewed in Fig. 18. When seated in this manner, the walls of the recess 364 secure the pad assembly against movement transverse the advancement axis 366 as a rotating disc is engaged. As best viewed in Fig. 5, it should be appreciated that the axial post 94 of the respective inboard or outside pressure foot 86, 134 is received within the receptacle 81 and the trailing surface 80 of the backing plates to thereby prevent withdrawal of the pad assembly from the mouth 362 of the cavity 360 with the brake pad seated as illustrated in Fig. 18. This connection is also the primary support against withdrawal along the engagement axis as the pad assembly is advanced and withdrawn by the actuation mechanism. The magnet 88 or 88' holds the backing plate in abutment with the respective pressure foot 86, 134 to maintain engagement between the axial post 94 and the receptacle 81. As the brake pads are advanced along the advancement axis, the cooperating engagement flanges 380 of the pad retention clip and the protrusions 376 of the pad retention tab define a rail facilitating movement forward and backward along the advancement axis. The pad clips can be easily removed from the orifice simply by manually advancing them inward along the advancement axis to bring the receptacle 81 out of engagement with the axial post 94 whereupon the engagement flanges 380 can be snapped out of engagement with the protrusions 376. As shown in Figs. 16A and 16B, the handle 392 has straight edges. To facilitate gripping, the handle may be modified

as shown in Figs. 17A-C. In Fig. 17A, the handle has a distal enlargement 395. In Fig. 17B, the handle has grooves 396. In Fig. 17C, the handle has knurls or bumps 397. Other grip enhancing structures will also be apparent to those skilled in the art.

The operation of the mechanical disc brake caliper 10 drive mechanism is best understood with reference to Figs. 1, 5, 6, and 7. Upon actuation of the lever arm 32 by tension applied to the cable 40, the lever arm rotates about the pivot axis 46 in the direction of arrow 48. This in turn causes rotation of the drive cam 158 about this same axis. As the drive cam 158 is rotated, the ball bearings 176 cause the drive cam to advance within the outside cylinder 128 which in turn advances the foot screw 148 which is threadably engaged with the drive cam. The leading surface 150 of the foot screw 148 in turn advances the ball bearing 146 and the outside pressure foot 134 to urge the pad 84 of the outside brake pad assembly 72 into contact with the disc. Further advancement will deflect the disc 14 into contact with pad 84 of the outside brake pad assembly 74, as illustrated in Fig. 7. Upon release of the tension in the cable, the lever arm is biased back to its at rest position by the return spring 228 and the pads are retracted out of contact with the disc to reassume the position illustrated in Fig. 5.

Fig. 10 illustrates that with the lever arm 32 in an at rest position, the cable extends between the cable clamp 38 and the cable feed 42 at a slight angle. With the lever arm 32 rotated about the pivot axis in the direction of arrow 48 so as to bring the pads into engagement with the disc, the lever arm advances axially along the advancement axis with the outer brake pad assembly 72 so that this slight angle is eliminated, as seen in Fig. 11. Thus, it is desirable that the axially flat, radially curved cable guide surface 332 be wide enough in the axial direction to accommodate the axial movement of the lever arm 32.

As the pads wear, it may be necessary or desirable to advance the pressure feet within the inboard and outboard cylinders to maintain the original spacing between the pads and the disc. The present invention provides a pad wear compensating apparatus that allows for such advancement (or retraction) by rotary to linear linkages between the knobs 106, 264 and the respective pressure feet 86, 134 and associated pads.

far the trailing end 156 of the indicator foot screw 148 advances relative to the outer surface of the outer knob 264 within the axial hole 268. To retract the pad, the outside knob is rotated counter-clockwise to retract the indicator foot screw 148 and the drive mechanism is actuated to squeeze the disc, which in turn retracts the outside pad assembly 72 and the outside pressure foot 134 by forcing them into abutment with the retracted foot screw 148.

The pad wear compensating apparatus not only allows for convenient advancement of the brake pad assemblies as the brake pads wear, but the structure also provides a quick and convenient way to properly align the caliper housing 18 relative to a disc 14. This can be done by loosening the mounting bolts 28 and then advancing the pad assemblies into contact with the disc using the inboard and outboard pad wear compensators 73, 153. With the disc squeezed between the pads, the mounting structure including the slotted mounting feet 20, 22 and the concave and convex washers 30 enables precise alignment of the caliper housing to maintain the leading pad surfaces parallel to the disc. Tightening the mounting bolts 28, 30 then secures the precise alignment. For example, because the inner pad assembly is stationary, it is generally preferred to provide a very small clearance between the inner pad and the disc and a greater clearance between the moveable outer pad and the disc. This set up can be achieved by starting with the pads fully withdrawn along the advancement axis into the cavity 360 as shown in Fig. 5 and then advancing the inner pad assembly using the inner knob a short distance while advancing the pad associated with the outer knob a greater distance into contact with the disc. The mounting bolts are then tightened and the knobs are turned to retract the pad assemblies to provide a desired operative gap with the disc.

While this greatly simplifies the process of properly aligning the caliper housing and brake pads during initial set up, the pad advancement structure in combination with the caliper housing mounting system also provide for simplified field repair. For example, if a user crashes and one of the attachment bosses is bent, the user can detach the mounting bolts 28, bend the bent attachment boss back in position as well as possible by eye-balling it and then reposition the caliper housing with the brake pads properly aligned parallel to the disc simply by repeating the procedure described in the preceding paragraph.

can be curled as illustrated in Fig. 25 to define a ball receiving socket 426. The legs 424 of each pair are radially spaced so that a ball bearing 176 can be snap fit therebetween as illustrated in Fig. 26. Figures 27 and 28 depict another embodiment of a ball spacer molded of plastic. Notches 427 in a ring 428 are sized to snap fit with the ball bearings 176. The ring is thick enough and the insides of the notch are slightly concave (see 429 in Fig. 27) to secure the ball bearing about an axis as illustrated in Fig. 28. Either ball spacer embodiment secures the ball bearings 176 about an axis and thus ensures that the ball bearings 176 will maintain an equal radial spacing and further ensures that the ball bearings will be the same distance between the face of the drive cam and the fixed cam.

The ramped groove structure of the fixed cam and drive cam illustrated in Figs. 4A and 4B is useful for most applications, but it limits the amount the lever arm can be rotated to, at most, slightly under 120° . An alternate ramp structure is depicted in Fig. 29. As illustrated in Fig. 29, the ramps 430 spiral inward as they ramp upward toward the leading surface 432. With such corresponding structures provided in the leading surface of the fixed cam and the drive cam, the ramped grooves 430 can be much greater in length and have a much more gradual incline. This will enable the associated lever arm 32 to rotate much greater than 120° and for the inboard brake pad to be advanced linearly at a slower rate as the lever arm 32 is pivoted.

The outer knob is shown in a perspective view in Fig. 19. The outer knob has an elongate slot 440 corresponding to each axially inwardly extending leg 270. Referring to Fig. 20, each elongate slot 440 overlies a corresponding barb 272. The holes 440 are formed during molding of the outer knob 264 by a mandrel which occupies the space that defines the hole 440, with the distal end of the mandrel contributing to the forming of the undercut of the barb. In this manner, the undercuts are introduced to the knob while still enabling the knob to be injection molded in a single step. Referring to Figs. 21 and 22, the inner knob 106 likewise has elongate slots 442 corresponding to each inward axially extending leg 112. As with the outer knob described above, the slots overly the barbs 114 and enable formation of the undercut on the barbs by means of mandrels as described above with regard to the inner knob.
